SOLUBILIZATION OF PROTEINS FOR PHARMACEUTICAL COMPOSITIONS USING POLYMER CONJUGATION

This invention relates to a chemical modification of biologically active proteins which alters the chemical and/or 5 physiological properties of these proteins. More specifically, this invention relates to selective conjugation of lipophilic water-insoluble proteins to polymers to render the proteins soluble at physiological pH.

Many heterologous proteins produced in microbial host cells 10 are found as insoluble material in refractile bodies. Examples of heterologous proteins which form refractile bodies in commonly found culture conditions include interleukin-2 (IL-2), interferon- β (IFN- β), feline leukemia virus (FeLV) envelope protein, human growth hormone (hGH), bovine growth hormone (bGH), porcine growth hormone (pGH), and 15 certain proteins coated or fused with a virus such as FMD virus. In addition, many of these proteins are hydrophobic in nature and tend to stick to materials and to themselves (i.e., aggregate) rather than remain in solution. Also, many of these recombinant proteins are unglycosylated, whereas their native counterparts are water-soluble, 20 glycosylated molecules. Modifications of these proteins which might alter their solubility properties would be desirable to increase production yields of these proteins as well as to facilitate their formulation for therapeutic use. In addition, modifications may reduce or eliminate aggregation of the protein when it is introduced 25 in vivo, thereby reducing its immunogenicity.

The use of polypeptides in circulatory systems for the purpose of producing a particular physiological response is well known in the medicinal arts. A limitation to the potential therapeutic benefit derived from the clinical use of polypeptides is their ability 30 to elicit an immune response in the circulatory system. This immune response may be caused by aggregates in the material prior to

injection as described by R. Illig (1970), J. Clin. Endocrin., 31, 679-688, W. Moore (1978), J. Clin. Endocrinol. Metab., 46, 20-27 and W. Moore and P. Leppert (1980), J. Clin. Endocrinol. Metab., 51, 691-697. This response involves the production of antibodies to the 5 polypeptides by the circulatory system into which they are injected. This antibody production may decrease or eliminate the desired biological function of the polypeptide, sometimes by causing reduced residence time in the circulatory system (reduced half-life) or by modifying the molecule by virtue of the antibody-polypeptide 10 interaction.

Modification of these potentially useful therapeutic polypeptides so as to preclude or at least reduce an immune response while still maintaining desired physiological activities of the polypeptide would allow the use of these polypeptides in the mammalian 15 circulatory system without the aforementioned disadvantages. In addition, due to the increased half-life of the circulating polypeptide, smaller amounts of the polypeptide would be required for the desired therapeutic effect than have heretofore been possible.

The problems of immunogenicity and short half-life in 20 circulation set forth hereinabove and other undesirable properties of certain proteins are well recognized and various modifications of polypeptides have been undertaken to solve them. These include the modification of proteins with substantially straight chain polymers such as polyethylene glycol (PEG) or polypropylene glycol (PPG). For 25 example, U.S. Patent No. 4,261,973 describes conjugation of immunogenic allergen molecules with non-immunogenic water-soluble polymers such as PEG to reduce the immunogenicity of the allergen. U.S. Patent No. 4,301,144 describes conjugation of hemoglobin to PEG, PPG, a copolymer of ethylene glycol with propylene glycol, or ethers, 30 esters or dehydrated products of such polymers to increase the oxygen-carrying ability of the hemoglobin molecule. European Patent Publication 98,110, published January 11, 1984, discloses that conjugating of a polypeptide or glycoprotein to a polyoxyethylene-polyoxypropylene copolymer increases the length of its physiological 35 activity. Preferably the polypeptide or glycoprotein is an enzyme or

native interferon, which are water soluble. U.S. Patent No. 4,179,337 discloses conjugating of water-soluble polypeptides such as enzymes and insulin to PEG or PPG to reduce the immunogenicity of the polypeptide while retaining a substantial proportion of its desired 5 physiological activity. U.S. Patent No. 4,002,531 discloses a different method of conjugating enzymes to PEG through an aldehyde derivative.

U.S. Patent 4,055,635 discloses pharmaceutical compositions comprising a water-soluble complex of a proteolytic enzyme linked 10 covalently to a polymeric substance such as polysaccharides.

U.S. Patent 3,960,830 discloses peptides bound to a polyalkylene glycol polymer such as polyethylene glycol.

U.S. Patent 4,088,538 discloses a reversibly soluble enzymatically active polymer enzyme product comprising an enzyme 15 covalently bonded to an organic polymer such as polyethylene glycol.

U.S. Patent 4,415,665 discloses a method of conjugating an organic ligand containing at least one primary or secondary amino group, at least one thiol group and/or at least one aromatic hydroxy group (described in col. 3, lines 19-36) to a polymeric carrier with 20 at least one hydroxyl group (described in col. 2, lines 42-66).

U.S. Patent 4,495,285 discloses a non-immunogenic plasminogen activator, the amino acid side chains of which are coupled to a polyalkylene glycol through a coupling agent.

U.S. Patent 4,412,989 discloses an oxygen-carrying material 25 containing hemoglobin or a derivative thereof covalently coupled through an amide bond to polyethylene or polypropylene glycol.

U.S. Patent 4,496,689 discloses a covalently attached complex of alpha-1-proteinase inhibitor with a polymer such as PEG or methoxypolyethylene glycols.

U.S. Patent 3,619,371 discloses a polymeric matrix having a biologically active substance chemically bound thereto.

U.S. Patent 3,788,948 discloses use of organic cyanate compounds to bind proteins to polymers.

5 U.S. Patent 3,876,501 discloses activation of water-soluble carbohydrates with cyanogen bromide to improve their binding to enzymes and other proteins.

U.S. Patent 4,055,635 discloses pharmaceutical compositions of a proteolytic enzyme linked covalently to a polymeric substance.

10 EP 152,847 discloses an enzyme conjugate composition comprising an enzyme conjugate, a calcium salt, and a polyethylene glycol.

JP 5792435 published November 26, 1982 discloses modified polypeptides where all or part of the amino groups are substituted 15 with a polyethoxyl moiety. DE 2312615 published September 27, 1973 discloses conjugating of polymers to compounds containing hydroxy or amino groups.

EP 147,761 discloses a covalent conjugate of alpha-1-proteinase inhibitor and water-soluble polymer, where the polymer may 20 be polyethylene glycol.

U.S. Patent No. 4,414,147 describes rendering interferon less hydrophobic by conjugating it to an anhydride of a dicarboxylic acid such as poly(ethylene succinic anhydride).

In addition to these patents and patent publications, 25 several articles discuss the concept of using activated PEG or PPG as a modifying agent for proteins such as enzymes, IgG and albumin. For example, Inada et al., Biochem and Biophys. Res. Comm., 122, 845-850 (1984) disclose modifying water-soluble lipoprotein lipase to make it soluble in organic solvents such as benzene by using cyanuric chloride 30 to conjugate with PEG. Takahashi et al., Biochem. and Biophys. Res. Comm., 121, 261-265 (1984) disclose modifying horseradish peroxidase using cyanuric chloride triazine with PEG to make the water-soluble enzyme active and soluble in benzene. Suzuki et al., Biochem.

Biophys. Acta, 788, 248-255 (1984) disclose suppression of aggregation of IgG using cyanuric chloride activated PEG. Abuchowski et al., Cancer Biochem. Biophys., 7, 175-186 (1984) state that modification of asparaginases from E. coli and Vibrio succinogenes using PEG activated by succinimidyl succinate increases the half-life and decreases the immunogenicity of the proteins. Davis et al., Biomedical Polymers, (New York: Academic Press, 1980), p. 441-451 disclose that enzymes normally insoluble may be solubilized by PEG attachment without further details. Several other articles discuss modification of enzymes such as uricase, streptokinase, catalase, arginase and asparaginase with PEG activated by succinimidyl succinate or cyanuric chloride to increase half-life and decrease the immunogenicity of the protein.

None of these references, however, disclose details on how to use a polymer modification process to water-solubilize recombinant proteins such as IL-2 and IFN- β which are hydrophobic and therefore resist formulation in an aqueous medium at physiological pH. Furthermore, it is not a priori possible to predict which selected proteins would be favorably responsive to treatment with polymers due to the vast difference in the pharmacokinetics and physical properties of various proteins. Furthermore, none of the references disclose reducing or eliminating aggregation of the protein, a phenomenon that elicits an immune response when the protein is introduced in vivo.

EP 154,316, published September 11, 1985 to Takeda Chemical Industries, Ltd., discloses and claims chemically modified lymphokines such as IL-2 containing PEG bonded directly to at least one primary amino group of a lymphokine.

Accordingly, the present invention provides for modifying those proteins selected from β -interferon, interleukin-2, and immunotoxins which are not ordinarily soluble in water under ambient conditions at pharmaceutically acceptable pH ranges to render them soluble in aqueous buffer under such conditions. This modification may be mimicking glycosylation of the protein, thereby surprisingly rendering the protein soluble as the native glycosylated protein is

soluble. This modification also avoids addition of extraneous solubilizing additives such as detergents or denaturants to keep the protein in solution. The modified protein retains the biological activity of the unmodified protein, both initially and over time.

5 As secondary advantages, the modification under some conditions increases the physiological half-life of the protein and may decrease its immunogenicity by reducing or eliminating aggregation of the protein or by masking antigenic determinants. It has also been found that this prolonged half-life is related to the efficacy of the
10 protein. The in vivo half-life can be modulated by selecting appropriate conditions and polymers.

More specifically, the present invention is directed to a pharmaceutical composition comprising a non-toxic, inert, pharmaceutically acceptable aqueous carrier medium in which is
15 dissolved a biologically active selectively conjugated protein selected from the group consisting of β -interferon, interleukin-2, and an immunotoxin, wherein the protein is covalently conjugated to a water-soluble polymer selected from the group consisting of polyethylene glycol homopolymers and polyoxyethylated polyols, wherein
20 said homopolymer is unsubstituted or substituted at one end with an alkyl group, and said polyol is unsubstituted, and wherein said protein in its unconjugated form is normally hydrophobic and not soluble in said aqueous carrier medium at pH 6-8 in the absence of a solubilizing agent.

25 Preferably the polymer is unsubstituted polyethylene glycol (PEG), monomethyl PEG (mPEG), or polyoxyethylated glycerol (POG), and it is coupled to the protein via an amide linkage formed from the 4-hydroxy-3-nitrobenzene sulfonate ester or the N-hydroxysuccinimide ester of a PEG, mPEG, or POG carboxylic acid.

30 Another aspect of this invention resides in a process for preparing a pharmaceutical composition comprising:

(a) preparing a water-soluble polymer having at least one terminal reactive group where the polymer is selected from the group consisting of polyethylene glycol homopolymers and polyoxyethylated

polyols, wherein said homopolymer is unsubstituted or substituted at one end with an alkyl group and said polyol is unsubstituted;

(b) reacting a biologically active normally hydrophobic, water-insoluble protein selected from the group consisting of β -5 interferon, interleukin-2, and an immunotoxin with the reactive group of said polymer so as to provide a water-soluble, biologically active, selectively conjugated protein; and

(c) formulating said protein in a non-toxic, inert, pharmaceutically acceptable aqueous carrier medium.

10 Figure 1 shows densitometry scans of 14% SDS-polyacrylamide gels for molecular weight analysis of PEG-modified (PEGylated) IL-2 obtained from reactions at 0, 10, 20, 50 and 100 moles activated PEG (PEG*) per mole of IL-2.

15 Figure 2 illustrates the solubility of PEGylated IL-2 compared to unmodified IL-2 at two different pHs by absorbance scan from 200 to 650 nm.

Figure 3 depicts the pharmacokinetics of PEGylated and unmodified IL-2 after intravenous injection into mice.

20 Figure 4 shows the pharmacokinetics of PEGylated and unmodified IL-2 after subcutaneous injection into mice.

Figure 5 shows densitometry scans of 14% nonreducing SDS-polyacrylamide gels for molecular weight analysis of PEGylated IFN- β obtained from reactions at 0, 10, 20 and 50 moles PEG* per mole of IFN- β .

25 Figure 6 illustrates the solubility of PEGylated IFN- β compared to unmodified IFN- β at two different pHs by absorbance scan from 200 to 650 nm.

As used herein, the term "normally hydrophobic, water insoluble" as describing the proteins refers to those proteins which 30 are insoluble or not readily soluble in water or an aqueous medium under ambient conditions of room temperature and atmospheric pressure at a pH of between about 6 and 8, i.e., at about neutral or

physiological pH. The modification herein acts to increase the solubility of such proteins when they are subjected to such physiological conditions. For purposes herein, solubility may be tested by (1) turbidity, as measured by spectrophotometric means,

5 (2) S value, as measured by ultracentrifugation, wherein the monomeric protein sedimentation rate rather than the much greater aggregate sedimentation rate signals solubility, and (3) apparent native molecular weight, as measured by size exclusion chromatography, wherein the soluble protein is closer to this value than the insoluble
10 protein. The exact numbers which would indicate solubility for each of these tests will depend on the type of buffer in which the protein is formulated, the pH of the buffer, and the ionic strength of the buffer.

The interferon- β and interleukin-2 herein may be obtained
15 from tissue cultures or by recombinant techniques, and from any mammalian source such as, e.g., mouse, rat, rabbit, primate, pig, and human. Preferably such proteins are derived from a human source, and more preferably are recombinant, human proteins.

The term "recombinant β -interferon," designated as IFN- β ,
20 preferably human IFN- β , refers to fibroblast interferon having comparable biological activity to native IFN- β prepared by recombinant DNA techniques as described in the art. In general, the gene coding for interferon is excised from its native plasmid and inserted into a cloning vector to be cloned and then into an expression vector, which
25 is used to transform a host organism, preferably a microorganism, and most preferably E. coli. The host organism expresses the foreign interferon gene under certain conditions to produce IFN- β . More preferably, the IFN- β is a mutein as described in U.S. Patent No. 4,588,585, in which the cysteine normally occurring at position 17 of
30 the wild-type or native molecule has been replaced by a neutral amino acid such as serine or alanine. Most preferably, the IFN- β mutein is IFN- β_{ser17} .

The term "recombinant interleukin-2," designated as IL-2, preferably human IL-2, refers to interleukin-2 having comparable biological activity to native IL-2 prepared by recombinant DNA techniques as described, e.g., by Taniguchi et al., Nature, 302:305-5 310 (1983) and Devos, Nucleic Acids Research, 11:4307-4323 (1983). In general, the gene coding for IL-2 is excised from its native plasmid and inserted into a cloning vector to be cloned and then into an expression vector, which is used to transform a host organism, preferably a microorganism, and most preferably E. coli. The host 10 organism expresses the foreign gene to produce IL-2 under expression conditions.

More preferably the IL-2 is a mutein as described in U.S. Patent No. 4,518,584, in which the cysteine normally occurring at position 125 of the wild-type or native molecule has been replaced by 15 a neutral amino acid such as serine or alanine. Alternatively or conjunctively, the IL-2 mutein may be one in which the methionine normally occurring at position 104 of the wild-type or native molecule has been replaced by a neutral amino acid such as alanine.

Preferably, the IL-2 is a protein produced by a 20 microorganism or by yeast which has been transformed with the human cDNA sequence of IL-2 which encodes a protein with an amino acid sequence at least substantially identical to the amino acid sequence of native human IL-2, including the disulfide bond of the cysteines at positions 58 and 105, and has biological activity which is common to 25 native human IL-2. Substantial identity of amino acid sequences means the sequences are identical or differ by one or more amino acid alterations (deletions, additions, substitutions) which do not cause an adverse functional dissimilarity between the synthetic protein and native human IL-2. Examples of IL-2 proteins with such properties 30 include those described by Taniguchi et al., supra; Devos, supra; European Patent Publication Nos. 91,539 and 88,195; U.S. Patent 4,518,584, supra. Most preferably, the IL-2 is ser₁₂₅IL-2, des-alal₁ser₁₂₅IL-2, des-alal₁IL-2, des-alal₁ala₁₀₄IL-2, or des-alal₁ala₁₀₄ser₁₂₅IL-2, where "des-alal₁" indicates that the N-terminal 35 alanyl residue of the IL-2 has been deleted.

The precise chemical structure of the proteins herein will depend on a number of factors. As ionizable amino and carboxyl groups are present in the molecule, a particular protein may be obtained as an acidic or basic salt, or in neutral form. All such preparations 5 which retain their bioactivity when placed in suitable environmental conditions are included in the definition of proteins herein. Further, the primary amino acid sequence of the protein may be augmented by derivatization using sugar moieties (glycosylation) or by other supplementary molecules such as lipids, phosphate, acetyl groups 10 and the like, more commonly by conjugation with saccharides. Certain aspects of such augmentation are accomplished through post-translational processing systems of the producing host; other such modifications may be introduced in vitro. In any event, such modifications are included in the definition of protein herein so long 15 as the bioactivity of the protein is not destroyed. It is expected, of course, that such modifications may quantitatively or qualitatively affect the bioactivity by either enhancing or diminishing the activity of the protein in the various assays.

Often the hydrophobic recombinant proteins such as IL-2 and 20 IFN- β produced from transformed host cells containing recombinant DNA precipitate inside the cell as opposed to being soluble in the cell culture medium. The intracellularly produced protein must be separated from the cellular debris and recovered from the cell before it can be formulated into a purified biologically active material. In 25 a process for isolating such a refractile material, the cell membrane of the transformed host microorganism is disrupted, greater than 99% by weight of the salts is removed from the disruptate, the desalted disruptate is redispersed, a material, preferably a sugar such as sucrose, is added to the disruptate to create a density or viscosity 30 gradient in the liquid within the disruptate, and the refractile material is separated from the cellular debris by high-speed centrifugation, i.e., at about 10,000 to 40,000 x g. Preferably, the salts are removed from the disruptate by diafiltration or centrifugation and sucrose is added to increase the density of the 35 liquid to about 1.1 to 1.3 g/ml.

After the centrifugation step, the pellet containing the refractile bodies is solubilized with a denaturant such as sodium dodecyl sulfate, the resulting suspension is centrifuged, and the supernate containing the protein is treated to isolate the protein.

5 The protein is separated from the supernate by appropriate means such as reverse-phase high pressure liquid chromatography (RP-HPLC) and/or gel filtration chromatography. After such separation, the protein is preferably oxidized to ensure the production of high yields of recombinant protein in a configuration most like its native

10 counterpart. Such oxidation is described in U.S. Patent No. 4,530,787 to Z. Shaked et al. The oxidation may also be carried out by reacting an aqueous solution containing a solubilized form of the protein at a pH between about 5.5 and 9 in the presence of air with at least an effective amount of an oxidation promoter containing a Cu^{+2} cation, as

15 described in U.S. Patent No. 4,572,798 to K. Koths et al. The preferred oxidation promoter or oxidant is CuCl_2 or $(\text{o-phenanthroline})_2\text{Cu}^{+2}$. After oxidation, the protein may optionally be desalted and purified further by RP-HPLC, dilution/diafiltration, S-200 gel filtration chromatography, and ultrafiltration techniques

20 before modification with activated polymer as described further hereinbelow. The polymer modification may, however, be carried out at any step after the heterologous protein has been isolated in sufficiently pure form to be biologically active for therapeutic purposes. The point at which the modification will occur will depend

25 on the ultimate purity of the protein required for the final pharmaceutical formulation and use.

The term "immunotoxin" as used herein to apply to the third class of proteins refers to a conjugate of an antibody and a cytotoxic moiety. The cytotoxic moiety of the immunotoxin includes a cytotoxic

30 drug or an enzymatically active toxin of bacterial or plant origin or an enzymatically active fragment ("A chain") of such a toxin. Examples of enzymatically active toxins and fragments thereof include diphtheria A chain, nonbinding active fragments of diphtheria toxin, exotoxin A chain (from Pseudomonas aeruginosa), ricin A chain, abrin A

35 chain, modeccin A chain, alpha-sarcin, Aleurites fordii proteins,

dianthin proteins, Phytolacca americana proteins (PAPI, PAPII, and PAP-S), momordica charantia inhibitor, curcin, crotin, saponaria officinalis inhibitor, gelonin, mitogellin, restrictocin, phenomycin, and enomycin. Ricin A chain, nonbinding active fragments of 5 diphtheria toxin, abrin A chain, and PAPII are preferred. Most preferred is the ricin A chain, which is modified by reaction with the polymer.

The antibodies employed in the immunotoxin are preferably monoclonal antibodies directed against a specific pathological 10 condition such as, e.g., cancers such as breast, prostate, colon or ovarian cancer, melanoma, myeloma, etc.

Conjugates of the antibody and cytotoxic moiety may be made using a variety of bifunctional protein modifying reagents. Examples of such reagents include N-succinimidyl-3-(2-pyridylidithio) propionate 15 (SPDP), iminothiolate (IT), bifunctional derivatives of imidoesters such as dimethyl adipimidate • HCl, active esters such as disuccinimidyl suberate, aldehydes such as glutaraldehyde, bis-azido compounds such as bis (p-azidobenzoyl) hexanediamine, bis-diazonium derivatives such as bis-(p-diazonium-benzoyl)-ethylenediamine, 20 diisocyanates such as tolylene-2,6-diisocyanate, and bis-active fluorine compounds such as 1,5-difluoro-2,4-dinitrobenzene.

The term "selectively conjugated" as used herein to apply to the protein refers to proteins which are covalently bonded via one or more of the amino acid residues of the proteins, depending mainly on 25 the reaction conditions, the ultimate use, the molecular weight of the polymer, and the particular protein employed. While the residues may be any reactive amino acids on the protein, such as one or two cysteines or the N-terminal amino acid group, preferably the reactive amino acid is lysine, which is linked to the reactive group of the 30 activated polymer through its free ϵ -amino group, or glutamic or aspartic acid, which is linked to the polymer through an amide bond.

In one preferred embodiment of the protein is covalently bonded via one or two of the amino acid residues of the protein, preferably lysines, for maximum biological activity. In another

preferred embodiment, the protein is covalently bonded via up to ten of the amino acid residues of the protein, preferably lysines, with higher substitutions generally increasing the circulatory life of the protein.

5 According to the process of this invention, the three types of proteins described above, which are normally hydrophobic and water insoluble, are rendered soluble in an aqueous carrier medium, preferably at a pH of about 5 to 8, more preferably about 6-8 and most preferably, 6.5-7.8, without use of solubilizing agents, by modifying
10 the proteins through conjugation to a specified polymer. If the protein is reacted through its lysine residues, the pH of the reaction is preferably about 7 to 9, more preferably 8-9. The success of such a modification of these proteins cannot be predicted from earlier use of polymer modification of water-soluble enzymes and hormones.

15 The polymer to which the protein is attached is a homopolymer of polyethylene glycol (PEG) or is a polyoxyethylated polyol, provided in all cases that the polymer is soluble in water at room temperature. Examples of polyoxyethylated polyols include, for example, polyoxyethylated glycerol, polyoxyethylated sorbitol,
20 polyoxyethylated glucose, or the like.

The glycerol backbone of polyoxyethylated glycerol is the same backbone occurring naturally in, for example, animals and humans in mono-, di-, and triglycerides. Therefore, this branching would not necessarily be seen as a foreign agent in the body.

25 The polymer need not have any particular molecular weight, but it is preferred that the molecular weight be between about 300 and 100,000, more preferably between 350 and 40,000, depending, for example, on the particular protein employed.

30 Preferably the PEG homopolymer is unsubstituted, but it may also be substituted at one end with an alkyl group. Preferably the alkyl group is a C₁-C₄ alkyl group, and most preferably a methyl group. Most preferably, the polymer is an unsubstituted homopolymer of PEG, a monomethyl-substituted homopolymer of PEG or polyoxyethylated glycerol, and has a molecular weight of about 350 to
35 40,000.

The protein is conjugated via a terminal reactive group on the polymer. The polymer with the reactive group(s) is designated herein as activated polymer. The reactive group selectively reacts with free amino or other reactive groups on the protein. It will be understood, however, that the type and amount of the reactive group chosen, as well as the type of polymer employed, to obtain optimum results, will depend on the protein employed to avoid having the reactive group react with too many particularly active groups on the protein. As this may not be possible to avoid completely, it is recommended that generally from about 0.1 to 1000 moles, preferably 2-200 moles, of activated polymer per mole of protein, depending on protein concentration, is employed. For IL-2 in particular, the amount of activated polymer employed is preferably no more than 50 moles per mole of IL-2, and most preferably is about 2 to 20 moles per mole of IL-2, depending on the specific properties ultimately desired, i.e., the final amount is a balance to maintain optimum activity, while at the same time optimizing, if possible, the half-life of the protein. Preferably, at least about 50% of the biological activity of the protein is retained, and most preferably 100% is retained.

The covalent modification reaction may take place by any suitable method generally used for reactive biologically active materials with inert polymers, preferably at about pH 5-9, if the reactive groups on the protein are lysine groups. Generally the process involves preparing an activated polymer (with at least one terminal hydroxyl group) and thereafter reacting the protein with the activated polymer to produce the solubilized protein suitable for formulation.

The above modification reaction can be performed by several methods, which may involve one or more steps. Examples of suitable modifying agents which can be used to produce the activated polymer in a one-step reaction include cyanuric acid chloride (2,4,6-trichloro-S-triazine) and cyanuric acid fluoride.

In a preferred embodiment the modification reaction takes place in two steps wherein the polymer is reacted first with an acid anhydride such as succinic or glutaric anhydride to form a carboxylic acid, and the carboxylic acid is then reacted with a compound capable 5 of reacting with the carboxylic acid to form an activated polymer with a reactive ester group which is capable of reacting with the protein. Examples of such compounds include N-hydroxysuccinimide, 4-hydroxy-3-nitrobenzene sulfonic acid, and the like, and preferably N-hydroxysuccinimide or 4-hydroxy-3-nitrobenzene sulfonic acid is 10 used. For example, monomethyl substituted PEG may be reacted at elevated temperatures, preferably about 100-110°C for four hours, with glutaric anhydride. The monomethyl PEG-glutaric acid thus produced is then reacted with N-hydroxysuccinimide in the presence of a carbodiimide reagent such as dicyclohexyl or isopropyl carbodiimide to 15 produce the activated polymer, methoxypolyethylene glycol-N-succinimidyl glutarate, which can then be reacted with the protein. This method is described in detail in Abuchowski et al., Cancer Biochem. Biophys., 7, 175-186 (1984). In another example the monomethyl substituted PEG may be reacted with glutaric anhydride 20 followed by reaction with 4-hydroxy-3-nitrobenzene sulfonic acid (HNSA) in the presence of dicyclohexyl carbodiimide to produce the activated polymer. HNSA is described in Bhatnagar et al., Peptides: Synthesis-Structure-Function, Proceedings of the Seventh American Peptide Symposium, Rich, et al. (eds.) (Pierce Chemical Co., Rockford 25 IL, 1981), p. 97-100, and in Nitecki et al., High-Technology Route to Virus Vaccines (American Society for Microbiology: 1986) entitled "Novel Agent for Coupling Synthetic Peptides to Carriers and Its Application."

As ester bonds are chemically and physiologically less 30 stable than amide bonds, it may be preferable to use chemical transformations in the conjugating reaction which would produce carboxylic acids or amides without concurrent production of esters.

The protein thus modified is then formulated in a non-toxic, inert, pharmaceutically acceptable aqueous carrier medium, preferably 35 at a pH of about 3 to 8, more preferably 6-8. For in vitro

applications, as for immunotoxins used for diagnostic purposes, the modes of administration and formulation are not critical. Aqueous formulations compatible with the culture or perfusion medium will generally be used. When used in vivo for therapy, the sterile product 5 will consist of a mixture of protein dissolved in an aqueous buffer in an amount which will provide a pharmaceutically acceptable pH when the mixture is reconstituted. A water-soluble carrier such as mannitol may optionally be added to the medium. The currently formulated unmodified IL-2 is stable for at least six months at 4°C.

10 The dosage level of protein in the formulation will depend on the in vivo efficacy data obtained after preclinical testing and will depend mainly on the protein employed and ultimate use.

If the formulation is lyophilized, the lyophilized mixture may be reconstituted by injecting into the vial a conventional 15 parenteral aqueous injection such as, e.g., distilled water.

The reconstituted formulation prepared as described above is suitable for parenteral administration to humans or other mammals in therapeutically effective amounts (i.e., amounts which eliminate or reduce the patient's pathological condition) to provide therapy 20 thereto, the type of therapy being dependent on the type of protein. For example, IL-2 therapy is appropriate for a variety of immunomodulatory indications such as T cell mutagenesis, induction of cytotoxic T cells, augmentation of natural killer cell activity, induction of IFN-gamma, restoration or enhancement of cellular 25 immunity (e.g., treatment of immune deficient conditions), and augmentation of cell mediated anti-tumor activity.

In an alternative to direct administration of IL-2, the IL-2 may be administered in an adoptive immunotherapy method, together with isolated, lymphokine-activated lymphocytes, in a pharmaceutically 30 acceptable carrier, where the lymphocytes are reactive to tumor when administered with the IL-2 to humans suffering from the tumor. This method is described more fully by S. Rosenberg et al., New England Journal of Medicine (1985), 313:1485-1492.

IFN- β therapy is appropriate for anti-cancer, anti-viral and anti-psoriasis treatment. Specific cancers against which IFN- β has shown some efficacy include lymphoma, myeloma, hairy-cell leukemia and some viral diseases including venereal warts and rhinoviruses.

5 Immunotoxin therapy is appropriate for diseases against which the targeted antibody is effective, usually cancer. In particular, immunotoxins are being targeted for such cancers as breast cancer.

The dose and dosage regimen of the immunotoxin will depend, 10 for example, upon the pharmacokinetics of the drug, the nature of the cancer (primary or metastatic) and its population, the type and length of polymer, the characteristics of the particular immunotoxin, e.g., its therapeutic index, the patient, and the patient's history. The dose and dosage regimen of the IL-2 and IFN- β will similarly depend, 15 for example, on the pharmacokinetics of the drug, the nature of the disease, the characteristics of the IL-2 or IFN- β , the patient and the patient's history. For example, different modified IL-2 proteins are expected to have different pharmacokinetic and therapeutic properties which are advantageous for different routes of administration. A 20 long-acting drug might only be administered every 3-4 days, every week or once every two weeks. The clearance rate can be varied to give ultimate flexibility to fit the particular need of the patient by changing, e.g., the type of polymer and the size of the polymer attached.

25 In the following examples, which illustrate the invention further, all parts and percentages are by weight unless otherwise noted, and all temperatures are in degrees Celsius.

EXAMPLE I

Preparation of PEGylated Interleukin-2 (IL-2)

30 A. Preparation of PEG-Ester.

A linear, monomethyl substituted ester of PEG of molecular weight 5000 can be obtained by first reacting monomethyl PEG-5000, which is commercially available, with glutaric anhydride at 100 to

110°C for four hours or by a method similar to that of Abuchowski et al., Cancer Biochem. Biophys., 7, 175-186 (1984). The resulting PEG-glutarate is reacted with N-hydroxysuccinimide in the presence of dicyclohexylcarbodiimide, as described in detail by Abuchowski et al., 5 supra, on page 176. The resulting product is methoxypolyethylene glycolyl N-succinimidyl glutarate, hereinafter designated as PEG*.

Similarly, succinic anhydride was reacted with monomethyl PEG-5000 and the resulting PEG-succinate was reacted with N-hydroxysuccinimide. The resulting product is methoxypolyethylene 10 glycolyl N-succinimidyl succinate.

In an alternative step, and by a similar method, a PEG carboxylic ester-HNSA was prepared using HNSA in place of N-hydroxysuccinimide. This ester preparation is described by Bhatnagar et al., supra and by Nitecki et al., supra. The PEG carboxylic ester-15 HNSA may be used as the activated PEG in the procedures described in this and subsequent examples.

B. Conjugating of PEG* to IL-2.

RP-HPLC purified recombinant des-alanyl, ser₁₂₅ IL-2 (where the cysteine at position 125 is replaced by serine and the N-terminal 20 alanyl residue is deleted), prepared as described in U.S. Patent Nos. 4,518,584 and 4,530,787, supra, or the post-diafiltered des-alanyl, ser₁₂₅ IL-2 from the production process described hereinabove, was employed for this example. To 0.5 mg of this purified IL-2 in 1.0 ml buffer (sodium borate, pH 9; 0.1% SDS) was added freshly prepared 25 aqueous PEG* in molar ratios of 0, 2.5, 5, 10, 20, 50 and 100 moles PEG* per mole of IL-2. After thorough mixing, the solutions were stirred at room temperature (23°C) for 30 minutes. Each reaction mixture was applied to a Sephadex G-25 column (Pharmacia) to separate IL-2 and PEG-IL-2 from low molecular weight species. The Sephadex G-30 25 column was run in 10 mM Na borate pH 9 containing no SDS and served also to remove most of the SDS from the protein. Most of the unmodified IL-2 and SDS was alternatively removed by adding the reaction mixture to a mixed bed ion retardation resin (Bio-Rad

AG11A8). The level of residual SDS in the PEGylated IL-2 samples, as measured by the acridine-orange test, as described by R. Sokoloff and R. Frigon, Anal. Biochem., 118, 138-141 (1981), was 3-7 μ g SDS per mg protein.

5 C. Purification of Modified IL-2.

Using hydrophobic exchange chromatography (Bio-Rad; Biogel-phenyl-5-PW), purified PEGylated IL-2 was obtained. A linear gradient with decreasing salt (Solvent A is 1.7 M $(\text{NH}_4)_2\text{SO}_4$ in 50 mM Na phosphate pH 7; 100-0% A in 15 min.) gave good separation of PEGylated 10 IL-2 and unmodified IL-2. Adding 10% ethanol to Solvent B and maintaining the column in an ice bath greatly enhanced the recovery and resolution, respectively, of PEGylated IL-2. Aliquots of the 15 fractions were assayed for IL-2 bioactivity (cell proliferation) by the methods generally described in Gillis, S., et al. J. Immunol., 120, 2027-2032 (1978).

EXAMPLE II

Characterization of PEGylated IL-2

A. Size characterization of modified IL-2 products from reactions with varying PEG to IL-2 molar ratios.

20 SDS-PAGE (14%) of the products from reactions described in Example I.A. containing 0, 10, 20, 50 or 100 moles PEG* per mole of IL-2 indicated an increasing degree of modification with increasing PEG* to IL-2 molar ratios. Densitometer scans of various gel lanes 25 were obtained using a Shimadzu Dual Wavelength Scanner (CS-930) as shown in Figure 1. The 10 PEG*/IL-2 and 20 PEG*/IL-2 samples showed a discrete species with an apparent molecular mass of approximately 25 kd in addition to small amounts of unmodified IL-2. At 50 PEG*/IL-2 and 100 PEG*/IL-2 there was a smear in the high molecular weight region, which is characteristic of extensively PEGylated proteins, and 30 there was no unmodified IL-2.

Size exclusion of the PEG-IL-2 solutions on a TSK-250 column (Bio-Rad; 25 x 0.4cm in PBS) provided further evidence of increasing modification with increasing PEG* to IL-2 ratios.

B. Radioactivity of PEGylated IL-2 as a Function of the Extent of Modification.

Fractions from the aforementioned Biogel-phenyl column elutions of IL-2 PEGylation reactions containing 0, 2.5, 5, 10, 20, 50 or 100 moles PEG* per mole of IL-2 were assayed by the IL-2 cell proliferation bioassay described in Example I.C. The results are increasingly in Table I. As more amino groups were modified, the IL-2 was increasing slowly inactivated. In reactions carried out at a molar ratio of 100 PEG*/IL-2, the specific activity of the modified IL-2 product was significantly lowered to only about 10% of that of unmodified IL-2.

TABLE I
Bioactivity of PEGylated IL-2 as a Function of the Extent of Modification

	<u>Mole of PEG-ester initially added per mole IL-2</u>	<u>Bioactivity (BRMP Standards Units/mg IL-2)</u>
15	1. 0 PEG*/IL-2	$7.36 \pm 4.83 \times 10^6$
	2. 2.5 PEG*/IL-2	$9.20 \pm 3.45 \times 10^6$
	3. 5 PEG*/IL-2	$11.50 \pm 2.30 \times 10^6$
	4. 10 PEG*/IL-2	$10.35 \pm 4.37 \times 10^6$
	5. 20 PEG*/IL-2	$7.82 \pm 2.76 \times 10^6$
	6. 50 PEG*/IL-2	$3.45 \pm 2.30 \times 10^6$
	7. 100 PEG*/IL-2	$0.69 \pm 0.23 \times 10^6$

25 *These numbers reflect a large variability in the IL-2 bioassay.

C. Solubility of PEGylated IL-2 compared to Unmodified IL-2.

After the modification reaction and subsequent Sephadex G-25 chromatography resulting in SDS removal, the pH of the PEGylated IL-2 was lowered to 6.5-7. The unmodified IL-2 in low SDS precipitated at 30 pH 5-7. The modified IL-2 from the reaction carried out at low molar ratios in relation to the amounts of PEG*/IL-2 in Table I had some turbidity, due to unmodified IL-2 which can be subsequently removed by AG11A8 resin or Biogel phenyl (HPLC) chromatography. The solution of modified IL-2 from higher molar ratios of PEG*/IL-2 remained clear

over time. The pH-adjusted solutions were ultracentrifuged (50,000 rpm, SW60 rotor, 12 hours at 5°C). The supernatants were removed and stored. Analysis of aliquots of both the residues and the supernatants by SDS-PAGE showed that the residues were unmodified IL-2 while the supernatants contained PEGylated IL-2. The dramatic difference in the solubility of PEGylated and unmodified IL-2 in the aqueous medium at neutral pH, in the absence of SDS or any other denaturants, is illustrated by the absorbance scans (Hewlett-Packard 8450A Spectrophotometer) in Figure 2. The unmodified IL-2 at pH 7 precipitates out of solution as evidenced by a loss of the characteristic spectrum.

Purified PEGylated IL-2 (after HPLC-phenyl column) was completely soluble at pH 7 in aqueous buffer without any detergent or denaturants. The purified PEGylated IL-2 remained in solution and retained its bioactivity over the time tested (at least five months). The PEGylated IL-2 which was soluble at neutral pH without SDS had the following specific activities compared to unmodified IL-2 in the presence of 0.1% SDS:

20	<u>Moles PEG* Initially Added Per Mole IL-2</u>	<u>Specific Activity (BRMP Standards Units/mg IL-2)</u>
	0	7.36 x 10 ⁶
	10	12.88 x 10 ⁶
	20	8.51 x 10 ⁶

NK (Natural Killer; described in U.S. Patent 4,518,584) and LAK (Lymphokine-Activated Killer; described in Grimm et al., J. Exp. Med., 155:1823-41 (1982)) activities of 10 PEG*/IL-2 and 20 PEG*/IL-2 were identical to those of unmodified IL-2. Addition of free PEG (4K daltons) in a 20-fold molar excess over unmodified IL-2 did not affect NK or LAK activities.

30 D. Stability of PEGylated IL-2 as a function of pH.

PEGylated IL-2 from a modification reaction using 50 moles PEG* per mole of IL-2 was incubated at various pH's at room temperature for three hours and then analyzed by 14% SDS-PAGE for

hydrolysis of the amide-linked PEG from the IL-2 polypeptide. PEGylated IL-2 was three-fold diluted in 10% acetonitrile containing 0.1% trifluoroacetic acid (pH 2.5), and also incubated at pH 7.5, 10 and 11. Alkaline pH's were attained by the addition of NaOH to sodium borate buffer at pH 9. No evidence of hydrolysis was obtained below pH 11 under these conditions. However, at pH 11, the PEGylated IL-2 was susceptible to hydrolysis. The observation that PEGylated IL-2 is stable at pH 2.5 for three hours at room temperature (20-23°C) is particularly useful in view of U.S. Patent No. 4,569,790 issued 10 February 11, 1986 describing a process for recovering IL-2 which involves an RP-HPLC step performed under similar conditions.

E. Pharmacokinetics of PEGylated IL-2 compared to unmodified IL-2 in mice.

1. Intravenous administration.

15 Pharmacokinetic data of unmodified IL-2 and two preparations of PEGylated IL-2 were obtained after intravenous administration of 12.5 µg of protein in D5W (5% dextrose in water) in each mouse in a total of 36 mice. Samples used for injections (100 µl bolus) are identified below and had the following activities.

	<u>Sample</u>	<u>IL-2 Activity (BRMP Standards Units/mg IL-2)</u>
A.	Unmodified IL-2 (lot LP-263)	$5.98 \pm 0.46 \times 10^6$
25 B.	PEGylated IL-2 (from 10 moles PEG [*] /mole IL-2 reaction)	$12.19 \pm 4.14 \times 10^6$
C.	PEGylated IL-2 (from 50 moles PEG [*] /mole IL-2 reaction)	$4.37 \pm 0.23 \times 10^6$

30 Sample A was rendered free from aggregated material by injection in D5W containing 0.1% SDS final concentration. The PEGylated IL-2 samples (B and C) contained no SDS because these are completely soluble without aggregation under normal aqueous conditions.

Each mouse from three groups of twelve female Balb/C mice was injected with one of the three samples into the tail vein and all were bled retro-orbitally at 1.5 min. At various later times after injection 100 μ l blood samples were removed retro-orbitally into 5 heparinized capillary tubes. Plasma was prepared immediately by centrifugation (1 min.) and an aliquot was diluted into assay medium for bioassay as described in Example I.C. Figure 3 shows the pharmacokinetics of unmodified IL-2 and two preparations of PEGylated IL-2 samples. The half-lives of the initial distribution of IL-2 from 10 Figure 3 (at 50% bioactivity) are the following:

<u>Sample</u>	<u>t 1/2</u>
A. Unmodified IL-2	2 min.
B. PEGylated IL-2 (10 PEG [*] /IL-2)	10 min.
C. PEGylated IL-2 (50 PEG [*] /IL-2)	35 min.

15 Thus, PEGylation of IL-2 results in a five-fold increase in circulating half-life in mice using 10 PEG^{*}/IL-2, as measured by cell proliferation assays, and a more dramatic 17-fold increase in circulating half-life using 50 PEG^{*}/IL-2.

When unmodified IL-2, PEGylated IL-2 (from 10 moles 20 PEG^{*}/mole IL-2 reaction) and PEGylated IL-2 (from 50 moles PEG^{*}/mole IL-2 reaction) were injected intravenously into twelve mice per each type of IL-2, the percent recovery of bioactivity of total injected units of IL-2 at 1.5 minutes after injection is indicated below:

25	<u>Sample</u>	<u>% Recovery of IL-2 Bioactivity</u>
	A. Unmodified IL-2	57
	B. PEGylated IL-2 (10 PEG [*] /IL-2)	72
	C. PEGylated IL-2 (50 PEG [*] /IL-2)	100

These results show a dramatic increase in percent recovery 30 of IL-2 bioactivity with the degree of modification by PEG^{*}, with 100% recovery occurring at the modification level of 50 moles PEG^{*} per mole IL-2.

2. Subcutaneous administration.

Pharmacokinetic data of unmodified and PEGylated IL-2 were obtained after subcutaneous administration in 48 mice of 12.5 µg protein in sterile water. Samples used for scapular subcutaneous injection (single 100 µl bolus) in mice included unmodified IL-2, PEGylated IL-2 (from 20 moles PEG*/mole IL-2 reaction), and PEGylated IL-2 (from 50 moles PEG*/mole IL-2 reaction). All three samples were at 0.125 mg/ml. The unmodified IL-2 sample contained 0.1% SDS due to its insolubility in aqueous solution at neutral pH.

At various time points 100 µl samples were removed retro-orbitally into heparinized tubes as previously described. Plasma was prepared and aliquoted for bioassay. The 45 min. time point had 16 mice for each of the three samples. All other time points had 2-5 mice per sample. Figure 4 shows the pharmacokinetics of unmodified and PEGylated IL-2's after subcutaneous injection into mice. Not only was the maximum percentage of the total IL-2 bioactivity injected found in the plasma much higher for the PEGylated molecules as indicated below, but the clearance rate of PEGylated IL-2 was significantly lowered (see Figure 4).

<u>Sample</u>	<u>Maximum % IL-2 Bioactivity Found in the Plasma</u>
A. Unmodified	0.5
B. PEGylated IL-2 (20 PEG*/IL-2)	7.0
C. PEGylated IL-2 (50 PEG*/IL-2)	17.5

25 F. Immune response in rabbits after injections of PEGylated IL-2 and unmodified IL-2.

The study had three groups, with four rabbits in each group.

Group A were rabbits injected with unmodified post-diafiltered des-alanyl, ser₁₂₅ IL-2 from the production process described hereinabove (lot LP 304). Group B were rabbits injected with PEG/IL-2 prepared from lot LP 304 using 20-fold excess PEG* as described above. Group C were rabbits injected with PEG/IL-2 also prepared from LP 304 using 50-fold excess PEG*. Each IL-2 preparation was diluted in sterile water prior to injection.

Female New Zealand White rabbits (weighing ~ 2.2 kg) were each injected intramuscularly at two sites, 0.5 ml (1-2 $\times 10^5$ units) per site of the appropriate IL-2 or PEGylated IL-2.

At various time intervals, all of the rabbits were bled from 5 the marginal ear vein or middle ear artery. The blood was allowed to clot and centrifuged to obtain serum. Aliquots of the sera were diluted 5-fold into IL-2 assay medium and bioassayed by the cell proliferation assay of Example I.C. The pharmacokinetic profiles of 10 IL-2 and PEGylated IL-2 in the circulating blood after intramuscular injection were similar to those obtained with mice.

One week after the above injections, all rabbits were given a second series of injections, intramuscularly, with the appropriate IL-2 or PEGylated IL-2. The units injected were the same as above.

Three weeks after the first injections, all rabbits were 15 boosted with the appropriate unmodified IL-2 or PEGylated IL-2 at 1-2 $\times 10^4$ units/kg. Antigen-specific antibody response was measured in the sera (obtained as described above) at regular intervals by ELISA assays, using horseradish peroxidase linked goat antirabbit IgG as the labeled reagent and orthophenylenediamine as the substrate. 20 Absorbance was measured at 492 nm. The antigens were coated on two types of ELISA plates, polystyrene and polyvinyl, obtained from Dynatech Laboratories, Inc. The antigens tested against the sera were unmodified IL-2 (LP 304), PEG/IL-2 (20-fold excess PEG*) and PEG/IL-2 (50-fold excess PEG*). The results at five weeks after the first 25 injections were as follows:

Group A These rabbits had all developed IL-2-specific IgMs, seen in dilutions to 10^4 - 10^5 in ELISAs. Two (A3 and A4) of the four rabbits also had high IL-2-specific IgGs up to 10^4 dilutions. Rabbit A2 had slightly lower levels of IgG. Rabbit A1 had the least IL-2-specific IgGs.

Group B These rabbits developed no detectable IL-2-specific IgGs. All had IL-2-specific IgMs detected to 10^2 dilutions in ELISA assays. These assays were repeated using PEG/IL-2 as the antigen on the ELISA plates, with the same result.

Group C These rabbits had no detectable IL-2-specific IgGs. All had IL-2-specific IgMs detected up to 10^2 dilutions in ELISA assays done with PEG/IL-2 as the antigen.

These studies indicate that the antigen-specific IgG response is reduced in the cases where PEG/IL-2 is the antigen, whereas with unmodified IL-2, antigen-specific IgGs are developed with time.

G. Efficacy studies of PEGylated IL-2 in Balb/c mice using a Meth A
In this experiment where mice were dosed daily, PEG/IL-2 was
10 strongly effective against Meth A sarcoma at doses where unmodified
IL-2 had only a slight effect.

66 Balb/c mice were each injected subcutaneously at the back
of the neck with 6×10^5 Methacholanthene-A (Meth A) mouse
fibrosarcoma tumor cell line, obtained from Sloan-Kettering as a cell
15 suspension from ascites fluid in Balb/c mice. The mice were
segregated into three groups with similar numbers of large, medium,
and small tumors (5-100 mm). The three groups were then injected
intraperitoneally with test material. Group A received 0.5 ml of PBS
containing 0.01 mg/ml PEG (monomethyl 5000). Group B received 0.5 ml
20 of tissue culture medium containing 10% calf serum + 3 μ g of the
PEG^{*}/IL-2 obtained using 20-fold excess of PEG^{*} over IL-2. Group C
received tissue culture medium containing 10% calf serum + 3 μ g of the
unmodified postdiafiltered des-al₁, ser₁₂₅ IL-2 as described above.

The three groups were injected daily for 7 days. The mice
25 were weighed and their tumor volumes measured on four days.

On day 8, the three groups differed in body weight.

PEG control	26.0 g
PEG*/IL-2	21.1 g
IL-2	23.6 g

	<u>Day 0</u>	<u>Day 6</u>	<u>Day 8</u>	<u>Day 9</u>
	Tumor Volume (mm ³)	Tumor Volume (mm ³)	Tumor Volume (mm ³)	Tumor Volume (mm ³)
10	Group A (PEG control excipient)	138+-48	3259+-919	5597+-1877
	Group B (PEG/IL-2)	129+-42	424+-129	341+-218
15	Group C (IL-2)	130+-63	2523+-808	2034+-997
				4405+-1471

On day 8, the mice treated with formulated IL-2 showed 64% tumor growth inhibition. However, by day 9 the inhibition was only 40% and the tumors were growing rapidly. The group was sacrificed to restrict suffering. The mice treated with PEG*/IL-2 showed 94% tumor growth inhibition both on day 8 and day 9. These mice also were sacrificed to restrict suffering.

EXAMPLE III

Preparation of PEGylated IL-2 With 350 Molecular Weight PEG

A. Preparation of PEG-Ester.

25 A linear, monomethyl-substituted ester of PEG of molecular weight 350 was obtained by the following method.

A total of 10 g monomethyl PEG-350 from Aldrich Chemical Co. was heated to 110°C. To this was added 14.3 g succinic anhydride (Aldrich). The mixture was stirred overnight at 110°C and then 30 cooled. Benzene was added and the benzene solution filtered. The reagent was isolated from the filtrate.

Two grams of the resulting PEG-350-succinate was mixed with 25 ml dimethyl formamide, 3.531 g dicyclohexylcarbodiimide and 6.914 g HNSA prepared as described in Example I. The mixture was stirred at room temperature for 48 hours in the dark and filtered. To the 5 filtrate was added slowly one liter of ether to precipitate the reagent. A total of 150 mg of the crude mix was added to 1 ml H₂O, centrifuged and decanted. The supernatant was applied to a Sephadex G-25 column in water and the appropriate fractions were pooled and lyophilized. The resulting purified product is designated hereinafter 10 as PEG*.

B. Conjugating of PEG* to IL-2.

The des-alanine₁₂₅IL-2 prepared as described in U.S. Patent Nos. 4,518,584 and 4,572,798, supra, was employed for this example. To 0.4 mg of this purified IL-2 in 1.0 ml buffer (0.1 M sodium borate, 15 pH 9, 0.1% SDS) was added freshly prepared aqueous PEG* in a molar ratio of 10 moles PEG* per mole of IL-2. After thorough mixing the solutions were stirred at 32°C for 15 minutes, 1 hour, 5 hours, and 20 hours. At each time point, 125 µl of the solution was removed and added to 40 µl of 1 mg/ml epsilon-NH₂-caproic acid and stored at 4°C.

20 C. Characterization of PEGylated IL-2.

SDS-PAGE (14%, reducing) analysis of the products from reaction B revealed that there was a substantial amount of modification which occurred by 15 minutes.

The PEG-350 IL-2 was active as tested by the IL-2 cell 25 proliferation bioassay in vitro mentioned above in Example I.C.

D. Pharmacokinetics of PEGylated IL-2 Compared to Unmodified IL-2 in Mice.

PEG-350 IL-2 and unmodified IL-2 were injected intravenously 30 into mice for pharmacokinetic analysis in a similar manner as described above in Example II.E. The results are shown in Table II.

TABLE II
Pharmacokinetics of PEGylated IL-2
(PEG-350 IL-2)

5	Time	BRMP Standards Units* / % Recovered	
		Unmodified IL-2	IL-2 PEG
	0 min. (total units injected)	176,913	80,046
	1.5 min.	81,880/ 46.3	25,035/ 31.3
10	8 min.	9602/ 5.43	3158/ 3.94
	20 min.	4950/ 2.80	2772/ 3.46
15	45 min.	1178/ 0.67	564/ 0.70
	1 hour	212(2)**/ 0.12	129/ 0.16
	2 hour	46(2)**/ 0.03	0
20	3 hour	0	0

*These units are units in mouse (BRMP units x 20-fold dilution)

**Parentheses indicate if there were fewer than 4 mice in the group.

EXAMPLE IV

25 Preparation of PEGylated IL-2 with 400 and
1000 Molecular Weight PEG

IL-2 derivatives of linear dihydroxy (unsubstituted) PEG of molecular weight 400 and 1000 were prepared generally by the method described in Example III using unsubstituted PEG-400 and PEG-1000, respectively.

30 **EXAMPLE V**

Preparation of PEGylated IL-2 with 10,000,
20,000 and 35,000 Molecular Weight PEG

An IL-2 derivative of linear, monomethyl-substituted PEG of molecular weight 10,000 was obtained generally following the method

described in Example I.A. using PEG 10,000 from Union Carbide. IL-2 derivatives of dihydroxy PEG of molecular weights 20,000 and 35,000 were obtained following a method similar to Abuchowski et al., supra, referred to in Example I.A. (using base in a solvent at room 5 temperature rather than an elevated temperature) using PEG-20,000 and PEG-35,000 from Fluka. The resulting modified IL-2 proteins were bioactive as assayed by the cell proliferation assay described above.

EXAMPLE VI

Preparation of PEGylated Interferon- β (IFN- β) Using PEG-5000

10 Preparation of activated PEG-ester and conjugation of the activated PEG-ester to RP-HPLC purified recombinant IFN- β where the cysteine residue at position 17 is replaced by a serine residue (ser₁₇ IFN- β), as described in U.S. Patent No. 4,518,584, were carried out 15 essentially as described for IL-2 in Example I.A. and I.B., in reactions containing 0, 10, 20 or 50 moles PEG* per mole of IFN- β . Separation of PEGylated IFN- β from unmodified IFN- β can be accomplished using molecular exclusion chromatography using a Sephadex S-200 column in 50 mM sodium acetate pH 5 with 0.1% SOS. 20 Aliquots from the S-200 fractionation were assayed for IFN- β antiviral activity using the cytopathic effect (CPE) assay method described generally by W.E. Stewart, "The Interferon System," Springer-Verlag, p. 17-18 (1979) and found to be active as described in Example VII. The CPE assay functions on the principle that interferon protects 25 cells treated therewith from the effects of virus. Cells more resistant to the virus will survive, whereas those which are sensitive to the virus will experience the cytopathic effect and die.

EXAMPLE VII

Characterization of PEGylated IFN- β Modified With PEG-5000

A. Size characterization of modified IFN- β products from reactions with varying PEG* to IFN- β molar ratios.

SDS-PAGE (14%, nonreducing) of the products from reactions described in Example VI containing 0, 10, 20 or 50 moles PEG* per mole

of IFN- β shows, as in the case of IL-2, an increasing degree of modification with increasing PEG* to IFN- β molar ratios. Densitometry scans (Figure 5) illustrate a decrease in the amount of unmodified IFN- β running at a molecular weight of 20,000 with increasing PEG* to IFN- β molar ratios. A discrete species with an apparent molecular weight of 30-35,000 was present after PEG-modification of IFN- β at all three molar ratios tested (10 PEG*/IFN- β , 20 PEG*/IFN- β and 50 PEG*/IFN- β). An increase in higher molecular mass species, probably representing more highly modified IFN- β molecules, was evident in the 10 reaction carried out at 50 moles PEG* per mole of IFN- β .

B. Bioactivity of PEGylated IFN- β compared to unmodified IFN- β .

Fractions of the S-200 separation of the PEGylated reactions containing 0, 10, 20 or 50 moles PEG* per mole of IFN- β were assayed for antiviral activity as described in Example III. The bioactivities 15 of PEGylated IFN- β obtained from all three modification reactions were comparable to unmodified IFN- β , as shown in Table III.

TABLE III
Bioactivities of Unmodified IFN- β and PEGylated IFN- β
As Measured by CPE Assay

20	<u>Mole of PEG* Initially Added Per Mole IFN-β</u>	<u>Bioactivity (Units/mg)</u>
	0	2.2 \pm 0.6 \times 10 ⁷
	10	2.2 \pm 1.6 \times 10 ⁷
	20	2.0 \pm 0.1 \times 10 ⁷
25	50	4.1 \pm 0.8 \times 10 ⁷

C. Solubility of PEGylated IFN- β Compared to Unmodified IFN- β .

After the modification reaction and the S-200 fractionation, SDS was removed using Sephadex G-25 chromatography similar to that described in Example I, all of the PEGylated IFN- β and the unmodified 30 IFN- β were each adjusted to pH 7. Whereas the PEGylated IFN- β remained in solution as indicated by absorbance scan from 200 to 650 nm, the unmodified IFN- β precipitated out of solution at pH 7 (Figure 6). Both modified and unmodified IFN- β were soluble at pH 9. Similar results were obtained for all PEGylated IFN- β samples tested.

D. Pharmacokinetics of PEGylated IFN- β Compared to Unmodified IFN- β .

In vivo half-life was improved similarly to that of IL-2 in rats and mice using PEGylated IFN- β versus unmodified IFN- β .

EXAMPLE VIII

5 Preparation and Characterization of PEGylated Ricin A

A. Preparation of PEGylated Ricin A Chain.

A soluble recombinant ricin A which requires no solubilization to be subjected to purification and to display cytotoxicity was prepared in accordance with the procedure described 10 as follows. When the coding sequence for ricin A was placed into direct reading frame with the DNA encoding leader sequence of phoA to form a putative fusion peptide, so that the leader sequence is the N-terminal portion of a leader/ricin A chimera, the ricin A sequences so disposed result in the soluble cytotoxic material.

15 Expression vectors containing the genes for the precursor proteins contained in pRT3 (ATCC Deposit No. 67,027 deposited March 7, 1986), pRT17 (ATCC Deposit No. 67,026 deposited March 7, 1986), and pRT38 (ATCC Deposit No. 67,025 deposited March 7, 1986) or their 20 mutagenized forms were constructed. Transforming host cells with these expression vectors resulted in solubilization of the precursor protein encoded. The arg-arg modified precursor was cleaved with trypsin; the A and B portions of the precursors were produced as separate proteins, as herein described.

In the phoA expression system, the essential component is 25 the terminated phoA leader sequence upstream of, proximal to, and out of frame with the ricin A encoding sequence, wherein the ricin A encoding sequence is initiated by an ATG codon. The two coding sequences must be, of course, provided with a compatible bacterial promoter, which was the phoA promoter already associated with the 30 leader. Additionally, production was improved in the presence of a positive retroregulator sequence which was the positive retroregulator sequences associated with the crystal protein of B. thuringiensis. This was provided on bacterial transport vectors which included replicons and selectable markers.

The vectors were then used to transform a suitable prokaryotic host, which was grown under conditions suitable for the particular host chosen, most frequently under conditions whereby the promoter placed in control of the expression system was suppressed.

5 The production of the ricin A was then induced by providing conditions which effect expression under control of the chosen promoter and the production permitted to proceed for sufficient time to effect a desired accumulation of product. The protein product was then isolated by disrupting the cells and the cellular debris was

10 removed. The ricin A produced was then further purified using standard techniques known in the art as applied to freely soluble proteins. However, the efficiency of the extraction and purification was enhanced by treating partially clarified extract with phenyl sepharose. The solubility of the ricin A in the sonicate (once

15 separated from the membrane or other associated materials) was shown by its ability to remain in the supernatant when the sonicate was subjected to centrifugation at high speed, 100,000 x g for 30 minutes, to spin down insoluble proteins.

A total of 2 ml of this soluble ricin A (at 9.0 mg/ml) was

20 rereduced by adding 2 μ l of fresh β -mercaptoethanol (to 0.1%) and incubating at room temperature overnight. The 2 ml of reduced ricin A was applied to a G-25 column (Pharmacia) equilibrated with 0.10 M NaPO₄ pH 8.0, followed by 0.5 ml of buffer to make 2.5 ml sample application volume. The next 3.0 ml of eluate (buffer was applied)

25 was collected as desalted ricin A.

1.0 ml of desalted ricin A (about 6 mg) was transferred to a 1.5 ml microfuge tube. To the ricin A was added 4.5 mg of N-hydroxysuccinimide ester of polyethylene glycol 2000 (activated PEG) obtained as described in Example I.A. The 4.5 mg of activated PEG

30 represented an 11-fold excess of the activated PEG over the ricin A.

The activated PEG was dissolved in the ricin A solution by gentle mixing. At various time points 100 μ l aliquots of the reaction mixture were desalted by the following procedure on G-25 columns to remove unreacted activated PEG and stop the PEGylation reaction:

100 μ l PEG/ricin A applied
2.4 ml 0.10 M NaPO₄ pH 8.0 applied
1.1 ml 0.10 M NaPO₄ pH 8.0 applied
and eluate collected as desalted ricin A

5 Time points taken were: 10', 20', 30', 45', 1 hour, 2 hours, 3 hours, 4 hours and 5 hours.

The reaction mixture was maintained on ice from time 0.

A 15% mini-gel was run to determine the degree of PEGylation. The results indicated that the PEGylation appeared to 10 have worked well and the reaction occurred quickly.

A new sample of PEGylated ricin A was prepared for conjugation to an antibody. About 40 mg of the ricin A described above was mixed with about 10 ml of Tris buffer, pH 8.5 with 1% β -mercaptoethanol. This was concentrated to about 5 ml and desalted in 15 an EDTA buffer on two G-25 columns to yield 6.37 ml total eluate. A total of 24.6 mg of N-hydroxysuccinimide ester of PEG (about 2000) was added to the ricin A and the mixture was allowed to react for 15 minutes on ice. (This amounts to a 10-fold excess of the activated PEG.)

20 The PEGylated ricin A was desalted over three G-25 columns, to yield a final eluate volume of 9.70 ml. β -Mercaptoethanol was added to 5 mM (about 0.05%). The PEGylated ricin A mixture was stored at 4°C.

A total of 50 μ g of PEGylated ricin A mixture was injected 25 into a preparative Zorbax GF-250 sizing column (DuPont) at a flow rate of 1 ml/min. using a buffer of 50 mM (NH₄)₂SO₄, 40 mM NaPO₄, pH 6.5.

The first peak was PEGylated ricin A, as determined by a 13.5% Minigel run of 5 ml fractions from a preparative fractionation.

The pool obtained in the first run was concentrated to about 30 2 ml and then purified by HPLC on a Zorbax GF-250 column by monitoring the absorbance at 280 nm. Fractions 15-23 of each run were pooled as PEGylated ricin A.

The molecular weight of the PEGylated ricin A was then determined by running a molecular weight standard (BioRad) on HPLC, under conditions similar to the purification method described above. A linear regression was performed, indicating that the PEGylated ricin A had apparent molecular weights of about 22 K (1-mer), 44 K (2-mer), and 59 K (higher mers).

B. Characterization of PEGylated Ricin A.

Aliquots from the 2 mg PEGylated ricin A Zorbax GF-250 run were tested for bioactivity in a reticulocyte assay (translation) 10 using a kit manufactured by Promega Brotec. The samples given were fraction 28 (high molecular weight), 34 (2-mer), 40 (1-mer), and some unpurified PEGylated ricin A/unmodified ricin A mix. The rabbit reticulocyte cell-free translation system assay measures protein synthesis by incorporation of radioactive methionine.

15 The results, shown in Table IV, indicated that only the purified 1-mer shows inhibition approaching that of free ricin A. The 2-mer and higher mer fractions showed greatly reduced inhibition as measured by elevated Inhibitory Doses at 50% (ID50).

TABLE IV

20	<u>Material</u>	<u>ID50 (ng/ml)</u>	<u>ID50 (M)</u>
	Ricin A	0.16	5.2×10^{-12}
	Higher molecular weight	158.5	5.2×10^{-9}
	2-mer	5011.9	-
	1-mer	3.16	103.6×10^{-12}

25 Thus, it appears that it may be necessary to PEGylate ricin only to produce 1-mers and to remove higher mers from the mixture.

The solubility benefit of the PEGylation was observed - the concentration of the PEGylated ricin A to 20 mg/ml which was achieved 30 was not possible using unPEGylated ricin A.

C. Conjugation of PEGylated Ricin A to Antibody.

A breast monoclonal antibody designated 520C9 was deposited as Accession No. HB8696 on January 8, 1985 in the American Type Culture Collection, Rockville, MD. This antibody was reacted with 5 5,5'-dithiobis-(2-nitrobenzoic acid) at room temperature and then chilled, and then sufficient 2-iminothiolane (IT) was added to give 2.5 IT molecules per antibody molecule.

A total of 166 μ l of propylene glycol was added to 0.84 ml of the IT-derivatized antibody. The 2.32 ml of PEGylated ricin A 10 chain described above was added to initiate the conjugation reaction. The mixture was incubated at room temperature for two hours.

The conjugation reaction mixture was applied to a Zorbax-GF-250 sizing (gel filtration) HPLC column using an eluting buffer of 15 0.15 M NaPO₄, pH 8.0. A total of 78% recovery of the purified immunoconjugate was obtained from the column.

D. Characterization of Conjugate.

1. Ribosomal Translation Assay.

The conjugate pool was filter-sterilized under a sterile 20 hood into a sterile tube from which aliquots were steriley pipetted into various sterile microfuge tubes. A 100 μ l aliquot of final sterifiltered immunotoxin was incubated with purified extracts from rabbit reticulocytes, ³⁵S methionine, mRNA and other factors for mRNA synthesis. The assay was measured without and with an inhibitor of 25 ribosomal translation. The dose response curve measures protein synthesis. Control samples included a conjugate of non-PEGylated immunotoxin, ricin A chain, and PEGylated ricin A chain. The results were as follows:

<u>Test Material</u>	<u>ID50 (M based on Ricin A Chain)</u>
Ricin A chain	5.9×10^{-12}
PEGylated ricin A chain	52.0×10^{-12}
5 Conjugate of ricin A chain and 520C9	60.8×10^{-12}
Conjugate of PEGylated ricin A chain and 520C9	141.0×10^{-12}

This assay indicated that the ID50 for PEGylated conjugate 10 and non-PEGylated conjugate was 15.85 and 7.94 ng/ml, respectively. Because the accuracy of this assay is no better than about +/- 100%, the inhibition for both is identical. It is apparent that addition of antibody alone to ricin A chain reduces the ID50 compared to non-conjugated ricin A. Thus, PEGylation does not impair ricin A activity 15 more than addition of antibody. PEGylation of the immunotoxin rather than just the toxin is expected to improve the results.

2. In Vitro Cytotoxicity Assay.

Forty thousand test breast cancer cells (from cell line SKBR3-publicly available) in 1 ml medium were added to a set of 8 ml 20 glass vials, followed by the addition of PEGylated and non-PEGylated conjugate dilutions (in phosphate buffered saline (PBS) containing 100 μ g/ml bovine serum albumin (BSA)). After incubation at 37°C for 22 hours, the medium was aspirated, the monolayers were washed with PBS, and methionine-free medium supplemented with 35 S methionine was 25 added. The vials were further incubated for two hours at 37°C, the medium was removed, and the cells were washed twice with 2 ml of 10% trichloroacetic acid containing 1 mg/ml methionine. The cells were dried, scintillation fluid was added, and the radioactivity was counted in a scintillation counter. Cytotoxicity was expressed as the 30 tissue culture inhibitory dose of conjugate that resulted in 50% of control (untreated) protein synthesis (TCID 50%).

The results of the assay were the following:

<u>Conjugate</u>	<u>TCID 50% (nM)</u>
Non-PEGylated	0.216
PEGylated	<0.422

5 The accuracy of this assay is also no better than about +/- 100%, and thus the TCID values of both are identical. With respect to cellular intoxication, the rate-limiting step does not appear to involve ricin A chain activity, but rather some other event, quite possibly conjugate binding, translocation, and/or intra-cellular
10 routing.

EXAMPLE IX

Preparation and Characterization of IL-2 Modified With Polyoxyethylated Glycerol (POG)

15 A. Preparation of Active POG-IL-2.

Polyoxyethylated glycerol (POG) of molecular weight 5000 was custom synthesized by Polysciences. To 10 g of POG was added 2.28 g glutaric anhydride (a ten-fold excess over POG). The mixture was stirred for two hours at 110°C and cooled. This was dissolved in 20 ml CHCl₃ and poured slowly into 500 ml ether with vigorous stirring. The product was collected and rinsed with ether to yield about 90% POG-glutarate product. This product was reacted with N-hydroxysuccinimide as described in Example I.A. to yield the active ester POG-glutaryl N-hydroxysuccinimide (POG*). Then 20 ml of 0.25 mg/ml IL-2 in 0.1 M sodium borate, pH 9, 0.1% SDS as described in Example I.B. was reacted with 5 mg of the POG* at room temperature for 30 minutes.

Ten ml of the reaction mixture was concentrated to 2 ml and applied to a Sephadex G-25 column in 10 mM sodium borate, pH 9. This 30 was adjusted to pH 7 (soluble) and concentrated. To 2 ml of the concentrate was added a solvent consisting of 1.7 M (NH₄)₂SO₄, 50 mM sodium phosphate, pH 7. This was then applied to a phenyl-TSK column at 0°C. The SDS-PAGE (14%, reducing) of the fractions indicated good separation.

The other 10 ml of POG-IL-2 was concentrated to 3 ml after adjusting to pH 5. This was applied to a Sephadryl S-200 column. SDS-PAGE (14%, reducing) of the fractions revealed a homogeneous POG-IL-2 product.

5 B. Characterization of POG-IL-2.

The fractions from the S-200 separation of the reaction mixture were assayed for bioactivity as described in Example I.C. The results are indicated in Table V.

TABLE V

	<u>Sample</u>	<u>Bioactivity (BRMP Standards Units/mg IL-2)</u>
10	Unmodified IL-2 (average)	12×10^6
15	Two pooled fractions with largest amount of POG-IL-2 (average)	15×10^6

Deposits

The plasmids with sequences used to prepare ricin A chain and the hybridoma which produces antibody 520C9 were deposited in the 20 American Type Culture Collection (ATCC), 12301 Parklawn Drive, Rockville, Maryland 20852-1776, USA. The ATCC accession numbers and deposit dates for the deposited samples are:

	<u>Vector/Hybridoma Designation</u>	<u>Deposit Date</u>	<u>Accession No.</u>
25	520C9	1/8/85	HB 8696
	pRT3	3/7/86	67,027
	pRT17	3/7/86	67,026
	pRT38	3/7/86	67,025

The deposits above were made pursuant to a contract between the ATCC and the assignee of this patent application, Cetus 30 Corporation. The contract with ATCC provides for permanent availability of the progeny of these plasmids and the cell line to the public on the issuance of the U.S. patent describing and identifying

the deposit or the publications or upon the laying open to the public of any U.S. or foreign patent application, whichever comes first, and for availability of the progeny of these plasmids and the cell line to one determined by the U.S. Commissioner of Patents and Trademarks to 5 be entitled thereto according to 35 USC §122 and the Commissioner's rules pursuant thereto (including 37 CFR §1.14 with particular reference to 886 OG 638). The assignee of the present application has agreed that if the plasmids and the cell line on deposit should die or be lost or destroyed when cultivated under suitable conditions, they 10 will be promptly replaced on notification with a viable culture of the same plasmids and cell line.

In summary, the present invention is seen to provide a pharmaceutical composition wherein a biologically active specific protein selectively conjugated to a PEG homopolymer or a 15 polyoxyethylated polyol and thereby made soluble or more soluble in an aqueous medium at physiological pH is dissolved in such medium. The conjugation serves not only to solubilize the normally hydrophobic water-insoluble protein in water at pH 6-8, but also increases its physiological half-life and may decrease its immunogenicity by 20 decreasing or eliminating aggregation of the normally hydrophobic protein or by shielding its antigenic determinants. Without the conjugation, the protein must be solubilized by addition of solubilizing agents such as detergents or denaturants, by raising the pH in combination with addition of a stabilizer or by lowering the pH.

25 The foregoing written specification is considered to be sufficient to enable one skilled in the art to practice the invention. The present invention is not to be limited in scope by the plasmids and cell line deposited, since the deposited embodiments are intended as a single illustration of one aspect of the invention and 30 any plasmids and cell lines which are functionally equivalent are within the scope of this invention. The deposit of materials herein does not constitute an admission that the written description herein contained is inadequate to enable the practice of any aspect of the invention, including the best mode thereof, nor are they to be 35 construed as limiting the scope of the claims to the specific illustrations which they represent.

WHAT IS CLAIMED IS:

1. A pharmaceutical composition comprising a non-toxic, inert, pharmaceutically acceptable aqueous carrier medium in which is dissolved a biologically active selectively conjugated protein selected from the group consisting of β -interferon, interleukin-2, and an immunotoxin, wherein the protein is covalently conjugated to a water-soluble polymer selected from the group consisting of polyethylene glycol homopolymers and polyoxyethylated polyols, wherein said homopolymer is unsubstituted or substituted at one end with an alkyl group and said polyol is unsubstituted, and wherein said protein in its unconjugated form is normally hydrophobic and not soluble in said aqueous carrier medium at pH 6-8 in the absence of a solubilizing agent.
2. A composition according to claim 1 wherein said polymer has a molecular weight of about 300 to 100,000.
3. A composition according to claims 1 or 2 wherein said polymer is conjugated to the protein via the 4-hydroxy-3-nitrobenzene sulfonate ester or the N-hydroxysuccinimide ester of a carboxylic acid of said polymer.
4. A composition according to any one of claims 1-3 wherein said polymer is an unsubstituted polyethylene glycol homopolymer, a monomethyl polyethylene glycol homopolymer or a polyoxyethylated glycerol.
5. A composition according to any one of claims 1-4 wherein said protein is a recombinant protein from a human source.
6. A composition according to any one of claims 1-5 wherein said protein is a recombinant protein from a human source.
7. A composition according to any one of claims 1-6 wherein said protein is a mutein.

8. A composition according to any one of claims 1-7 wherein said protein is $\text{ser}_{125}\text{IL-2}$, $\text{des-ala}_1\text{IL-2}$, $\text{des-ala}_1\text{ser}_{125}\text{IL-2}$, $\text{des-ala}_1\text{ala}_{104}\text{IL-2}$, $\text{des-ala}_1\text{ala}_{104}\text{ser}_{125}\text{IL-2}$, $\text{ser}_{17}\text{IFN-}\beta$, or an immunotoxin with a recombinant ricin A chain.

5 9. A composition according to any one of claims 1-8 wherein said protein is selectively conjugated via one to ten lysine residues on the protein.

10. A process for preparing a pharmaceutical composition comprising:

10 (a) preparing a water-soluble polymer having at least one terminal reactive group, where said polymer is selected from the group consisting of polyethylene glycol homopolymers and polyoxyethylated polyols, wherein said homopolymer is unsubstituted or substituted at one end with an alkyl group and said polyol is unsubstituted;

15 (b) reacting a biologically active normally hydrophobic, water-insoluble protein selected from the group consisting of β -interferon, interleukin-2, and an immunotoxin with the reactive group of said polymer so as to provide a water-soluble, biologically active, selectively conjugated protein; and

20 (c) formulating said protein in a non-toxic, inert, pharmaceutically acceptable aqueous carrier medium.
